

A NEW SPECIES OF *NARATHURA* FROM BORNEO  
(LEPIDOPTERA : LYCAENIDAE)

HISAKAZU HAYASHI

5-2, Tamatsukuri-honmachi, Tennoji-ku, OSAKA 543

Among Bornean Lycaenid butterflies preserved in Meijo University, I found a *Narathura*-species which resembled *Narathura antimuta* Felder but was unknown to me. As a result of further studies, I have concluded that this specimen belongs to a new species. The holotype is to be preserved in the Osaka Museum of Natural History.

*Narathura aritai* H. Hayashi, sp. nov. (Figs. 1-6)

♂. Not tailed. Upperside shining dark violet blue, with black border about 1 mm. Underside hair brown. Markings faint, slightly darker than the ground. Forewing post-discal band partially dislocated at vein 4 and the upper portion oblique. Hindwing post-discal band completely dislocated at vein 2. No tornal green scales.

Forewing length 16 mm.

Male genitalia : Brachia stout, hammer-like in shape, but strongly broadened in the middle towards apex, with blunt tip. Valvae with posterior margin split in two lobes. Phallus slender and long, slightly curved dorsally. Juxta M-shaped. Genitalia are closely related to those of *antimuta*, but is mainly different in the shapes of brachia and phallus.

♀. Unknown.

Distribution : Borneo

Holotype ♂, Kuala Bok, Sarawak, 4 March 1969, T. Kunou and Y. Arita leg.

The present new species belongs to *perimuta* group and is closest to *antimuta*, but this new species differs in having wider borders on upperside as well as in lacking green tornal markings on underside hindwing.

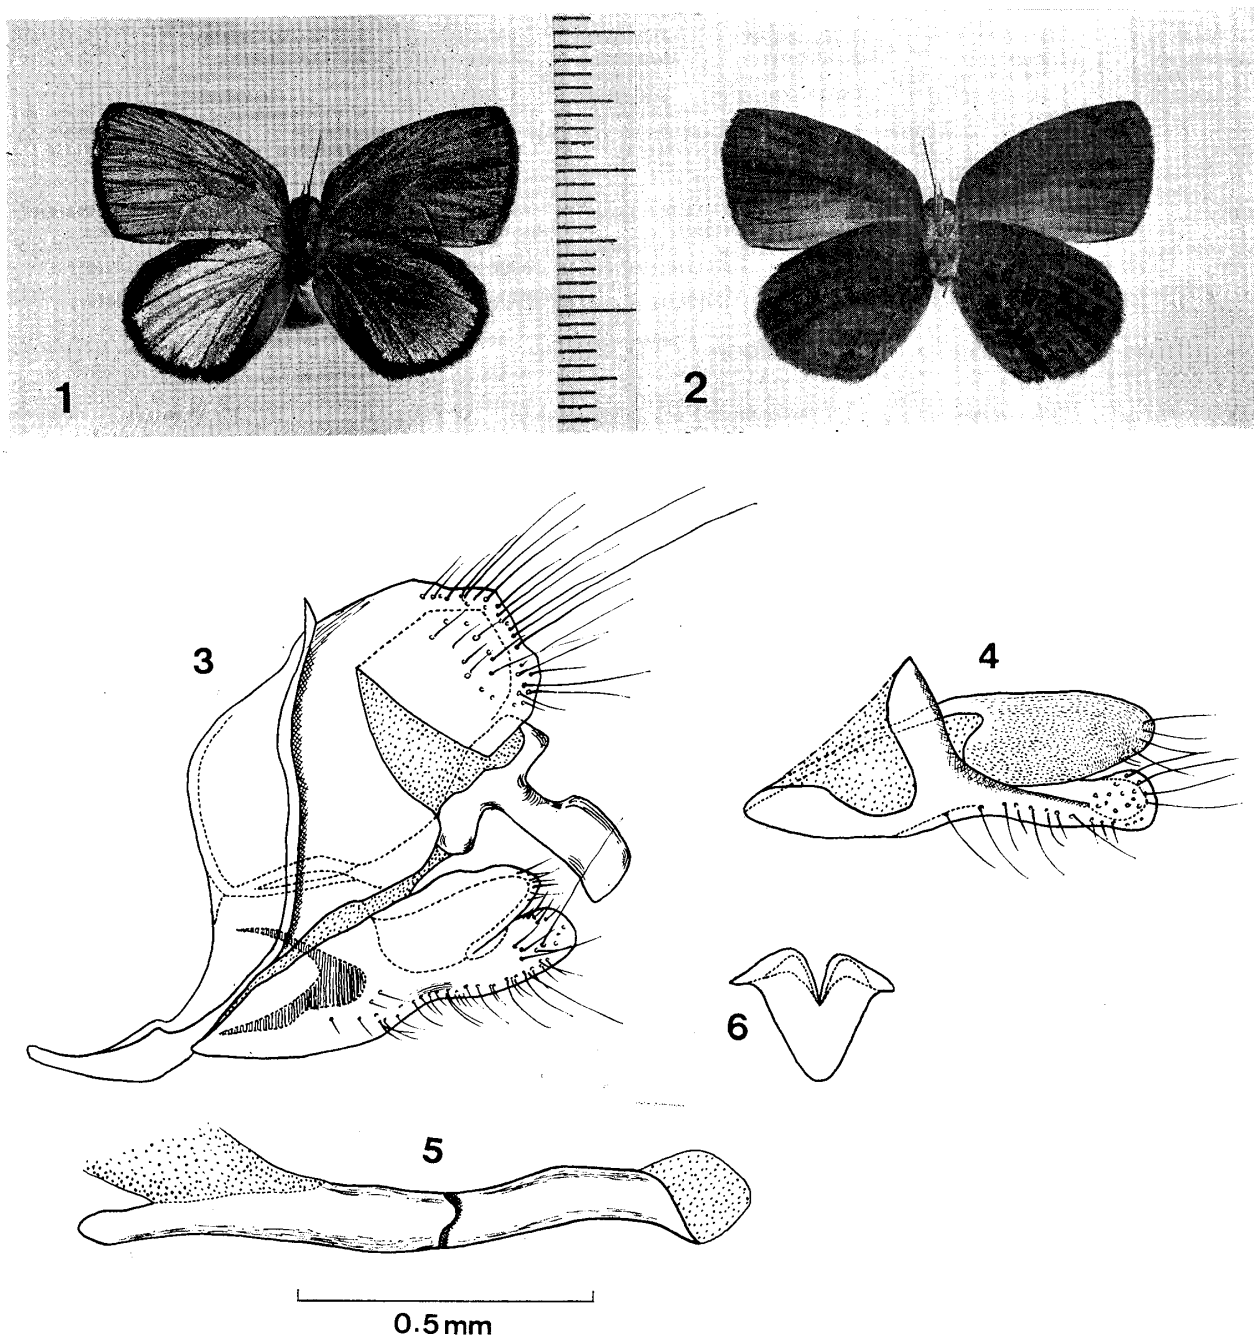

I name this species after Assistant Prof. Yutaka Arita who collected the specimen during his expedition to Borneo.

Acknowledgments

I have to thank Lt. Col. J. N. Eliot and Mr. A. Kawazoé for their kindness in giving helpful advice. My hearty thanks are also due to Assistant Prof. Y. Arita of Meijo University for his kindness in giving me the chance to study the material.

摘 要

名城大学所蔵のボルネオ産シジミチョウの標本中に *Narathura antimuta* Felder に似た未知種を見出したので、ここに新種として記載した。(林 寿一)
